

Exercices on session *Data visualisation*

Graphical exploration on wood density data

For this part, there is no need to improve the appearance of the plots.

Let's work with the *wdData* from a previous version of the package *BIOMASS* (v 2.1.11). These data are available [here](#), and the metadata [here](#).

- Read these data as a tibble
- Make a histogram of wood density for each of the following three regions, using facets: South_America_(tropical), Australia/PNG_(tropical), Africa_(tropical)
- Represent the same data but with a single density plot
- Compare the distribution of wood density for the 10 more common family on a single graph
- Show the number of observation per *family* and *regionId* for the 10 most abundant families

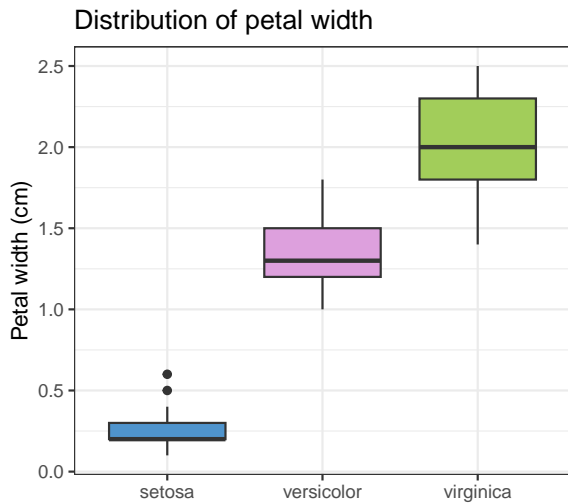

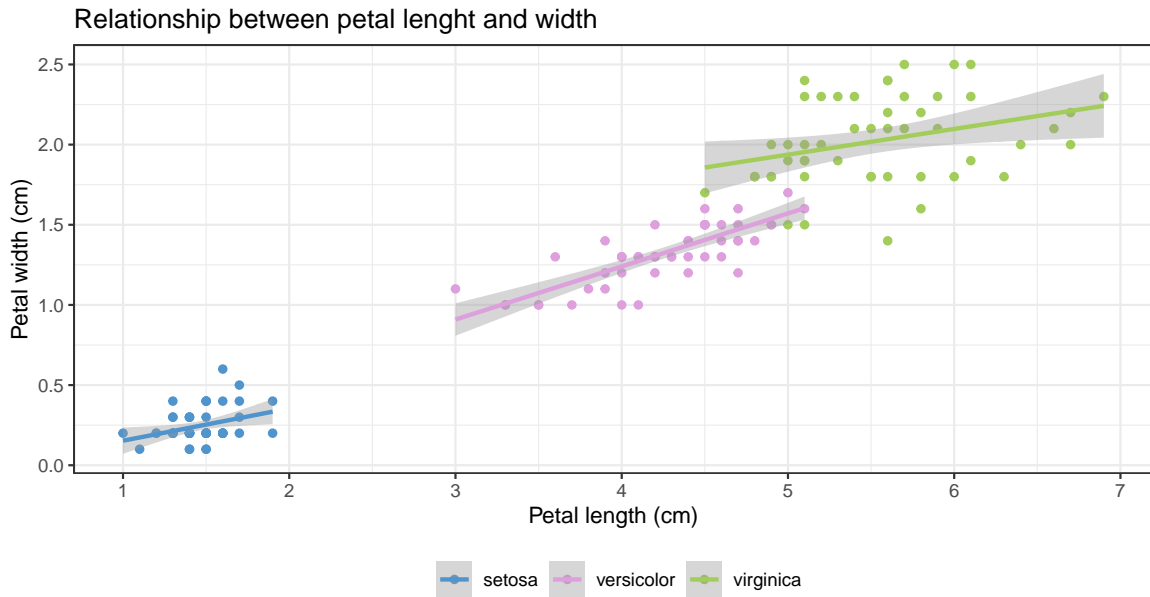

Iris data

Let's now work with the *iris* dataset (available from *datasets*, which is a package automatically loaded with R, you don't need to install it).

“This famous (Fisher's or Anderson's) iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are Iris setosa, versicolor, and virginica.”

Reproduce the following graph made with the *iris* dataset.

The colours are *steelblue3*, *plum* and *darkolivegreen3* and the theme *bw*.

For next time

- Make sure you remember what we saw on descriptive statistics in the session *Working with data*
- Install the following packages from CRAN: *multcompView*, *GGally*
- Make sure you have the following packages: *questionr*, *tidyverse*, *BIOMASS*

- Download the *RData* file available [here](#) and store them in your raw data folder.
